

What are the components of a capacitive power supply?

Full-wave bridge rectifier circuit. Voltage regulator circuit. Power indicator circuit. A capacitive power supply has a voltage dropping capacitor (C1), this is the main component in the circuit. It is used to drop the mains voltage to lower voltage. The dropping capacitor is non-polarized so, it can be connected to any side in the circuit.

What type of power supply uses a capacitive reactance?

This type of power supply uses the capacitive reactance of a capacitor to reduce the mains voltage to a lower voltage to power the electronics circuit. The circuit is a combination of a voltage dropping circuit, a full-wave bridge rectifier circuit, a voltage regulator circuit, and a power indicator circuit.

How many circuits are there in a capacitive power supply?

$Z = \sqrt{R^2 + X^2}$  Schematic of capacitive power supply circuit shown below. The working principle of the capacitive power supply is simple. From the Capacitive power supply circuit diagram we can observe the circuit is a combination of four different circuits. Voltage dropping circuit. Full-wave bridge rectifier circuit. Voltage regulator circuit.

What is a regulated power supply?

Testing of the completed power supply is described along with results, conclusions and references. The key takeaways are that a regulated power supply is used to provide a constant DC voltage output irrespective of changes in input voltage or load. It discusses the main components like transformer, rectifier, capacitor and adjustable regulator.

How to choose a voltage dropping capacitor for capacitive power supply?

Selection of the voltage dropping capacitor for capacitive power supply, some technical knowledge, and practical experience requires to get the desired voltage and current output. An ordinary capacitor will not do the same job since the mains spikes will make holes in the dielectric, and the capacitor will fail to work.

Is a capacitive power supply safe?

No! The capacitive power supply is not safe for us. Because, when this power supply is on no-load, no current flowing through the circuit, and no voltage drop in the capacitor. Otherhand, there is no isolation from the mains. So, if we touch the circuit, we will get an electric shock from it.
