

How do you charge a super capacitor?

Most super capacitors (supercaps) can be discharged down to 0 V and recharged to their maximum voltage with the manufacturer recommended charge current. A simple voltage regulating LED driver with constant current, usually regulated by sensing a low side, series current sense resistor, then a voltage clamp can be used to charge a super capacitor.

Why does a super capacitor charge at a constant voltage?

Eventually, the super capacitor voltage, and therefore the charging circuit's operating efficiency, increases so the capacitor charges at the desired constant (fast or max) charge current, ICHG, until it reaches and remains at constant voltage (CV) regulation voltage, VREG.

What is high-voltage capacitor charging?

High-voltage capacitor charging made simple tor charger or power supply up to a thousand volts is not a trivial task. A discrete solution uses a general-purpose flyback PWM (pulse-width modulation) controller with an optocoupler, monitoring, status and protection features.

What voltage should a pulse operated capacitor be charged to?

I have a semi-serious hobby project with a couple of friends where we need to charge a pulse operated capacitor rated to around 4kV with 1500nF capacitance. You didn't say exactly what voltage you wanted to charge the capacitor to, but generally speaking you shouldn't go all the way up to the rating if you want the device to be reliable.

Is it safe to experiment with high voltage capacitors?

Storing high voltage in large capacitors represents a LOT of energy, that can very quickly and easily kill you. High voltage experiments should only be conducted after a good deal of learning and experience has been accomplished in low power, low voltage circuits. I much prefer for "newbies" to restrict their experiments to below 50v.

What is the maximum voltage of a super capacitor?

The maximum voltage of a single layer super capacitor is typically 2.7 V, which leads to a usable capacitor voltage range of 1.9 V to 2.7 V. Figure 3 shows the basic flow of a recharge cycle. Most of the time the voltage is kept at 1.9 V to minimize the losses of the micro-controller and other leakage currents in the application (Phase 1).

A capacitor charger or capacitor charging power supply is a part of pulse power system. It provides controllable high voltage DC output to charge capacitors in order to store electrical energy in a system over a long time. Later the energy could be released over a short time, a huge amount of peak power can be delivered to a load.

This avoids overvoltages, if you run Uzzors2k's circuit without a capacitor load the chances are the circuit gets damaged. The low inductance of the primary helps to reduce voltage peaks, if the ...
