

Should electric vehicle manufacturers increase battery driving range?

Increasing the battery driving range level seems to hold the most potential for the electric vehicle manufacturer (EVM), but it is an expensive tool for the BS who is in charge of making the investment.

Does battery capacity affect driving range?

Nevertheless, battery capacity has also increased from 43 kWh to 82 kWh (an increase of 90.6%), resulting in a significantly high battery cost. Obviously, relying on stacking battery capacity in exchange for driving range improvement is inadvisable. Table 1. On-board battery capacity and driving range of main BEV models .

How Bs can improve battery driving range?

Considering consumers' sensitivity to the battery driving range, the BS can improve the driving range level by investing, and obtain subsidies if the driving range level exceeds the subsidy threshold set by the government. Meanwhile, the BS may misreport his private information of the investment cost to the EVM.

Should the BS upgrade the battery driving range level?

To encourage the BS to upgrade the battery driving range level, the government will raise the subsidy threshold, which also means that the BS needs to make more efforts to get subsidies. Based on this, we examine two choices of the BS: no improvement vs. improvement.

Why are battery driving range levels raised?

Therefore, the extent to which the battery driving range level is raised is the result of a trade-off between the investment cost, consumers' preferences for EVs with high driving range and the subsidy threshold set by the government, which is not clear.

Can high-capacity batteries extend EV driving range?

Inevitably, demand is growing for high-capacity batteries that can extend EV driving range. Recently, a joint team of researchers from POSTECH and Sogang University developed a functional polymeric binder for stable, high-capacity anode material that could increase the current EV range at least 10-fold.

The lithium-air battery uses a solid electrolyte instead of the typical liquid variety, potentially boosting the battery's energy density by as much as four times above Li-ion batteries, which translates into a longer driving

Silicon-based anode materials could potentially increase driving range at least tenfold."

The driving range of a BEV with a function of the pack energy density is plotted in Fig. 5 a. The linear relationship between driving range and battery energy density is approximately justified by recently released BEVs. This analysis indicates that 1,000 km EVs requires an energy density of 312 Wh kg⁻¹ in pack level.
