

# What is the appropriate activation current for lithium batteries

Do lithium-ion batteries use pulse current?

In this review, we summarize the usage of pulse current in lithium-ion batteries from four aspects: new battery activation, rapid charging, warming up batteries at low temperature, and inhibition of lithium dendrite growth.

## 1. Introduction

What is the target charge current for a lithium ion battery?

This target charge current is relative to the battery capacity ("C"). For standard Li-ion or Li-polymer batteries, chargers often target 0.5C charge current. In other words, if the battery is rated at 500 mA-h, the target current is 250 mA. It is not unusual to charge at 1C (500mA), but this compromises the battery's capacity over time.

Why is a lithium ion battery formation process important?

With precise formation process performance, formation time for each battery cell can be optimized. The highly efficient energy recycling feature enables significant energy saving for large scale battery manufacturing. Lithium ion (Li-Ion) manufacturing is a long process, as shown in Figure 1.

Can lithium ion battery charge faster without lithium deposition?

The aim of this research is to provide an optimal charge current of lithium ion battery, by which the theoretically fastest charging speed without lithium deposition is able to be reached. In other words, a maximal acceptable charge current of lithium ion battery is proposed.

How can pulse current charging improve the electrochemical performance of lithium battery?

Furthermore, a proposal to further enhance the effect of pulse current charging method is given, that is, the anion of the low coordination number should be selected to match with the lithium ion to promote the diffusion of Li and finally improve the electrochemical performance of the lithium metal battery.

When does a lithium ion battery charge end?

**Charging Termination:** The charging process is considered complete when the charging current drops to a specific predetermined value, often around 5% of the initial charging current. This point is commonly referred to as the "charging cut-off current."
